

HATCHERY AND GENETIC MANAGEMENT PLAN (HGMP)

Hatchery Program:	Hood Canal Fall Chinook Yearling Program
Species or Hatchery Stock:	Fall Chinook (<i>Onchorynchus tshawytscha</i>) Hood Canal
Agency/Operator:	Washington Department of Fish and Wildlife
Watershed and Region:	Hood Canal Puget Sound
Date Submitted:	, 2002
Date Last Updated:	August 20, 2002

SECTION 1. GENERAL PROGRAM DESCRIPTION

1.1) Name of hatchery or program.

Hoodsport Hatchery Fall Chinook - Yearling Program

1.2) Species and population (or stock) under propagation, and ESA status.

Hood Canal Fall Chinook (*Oncorhynchus tshawytscha*)

1.3) Responsible organization and individuals

Name (and title): Manuel Farinas, Operations Manager
Denis Popochock, Complex Manager
Agency or Tribe: Washington Department of Fish and Wildlife
Address: 600 Capitol Way North, Olympia, WA 98501-1091
Telephone: (360) 902-2714 (360) 427-2214
Fax: (360) 902-2943 (360) 427-2215
Email: farinmaf@dfw.wa.gov popocdap@dfw.wa.gov

Other agencies, Tribes, co-operators, or organizations involved, including contractors, and extent of involvement in the program:

In addition to WDFW production, Long Live the Kings (LLTK) has been contracted to produce yearling fall chinook under the Puget Sound Recreational Enhancement Program at LLTK's Lilliwaup Hatchery.

1.4) Funding source, staffing level, and annual hatchery program operational costs.

All yearling fall chinook production in Hood Canal is funded through the Puget Sound Fishery Recreational Enhancement Program.

1.5) Location(s) of hatchery and associated facilities.

Hoodsport Hatchery: Located at the mouth of Finch Creek (16.0222) on Hood Canal in the town of Hoodsport, Washington. Basin name: Hood Canal

1.6) Type of program.

Isolated harvest

1.7) Purpose (Goal) of program.

Augmentation

The goal of Hood Canal yearling fall chinook is to provide fish for sport harvest opportunity within Hood Canal and Puget Sound.

1.8) Justification for the program.

This program will be operated to provide fish for harvest while minimizing adverse effects on listed fish. This will be accomplished in the following manner:

- 1) Yearling chinook will be released as smolts to minimize emigration time to saltwater thereby minimizing potential competition with and predation on natural-origin listed fish.
- 2) Yearling chinook will be released at the appropriate time to minimize potential adverse interactions with wild chinook.
- 3) All yearling chinook released will be acclimated at a hatchery facility capable of trapping the majority of returning adults. This practice will minimize straying and make possible the removal or regulation of hatchery fish allowed to spawn naturally.
- 4) Adult chinook produced from this program will be harvested at a rate that allows adequate escapement of listed chinook.

1.9) List of program “Performance Standards”.

1.10) List of program “Performance Indicators.”

Performance Standards and Indicators for Puget Sound **Isolated Harvest** Chinook programs.

Performance Standard	Performance Indicator	Monitoring and Evaluation Plan
Produce adult fish for harvest	Survival and contribution rates	Monitor catch and cwt data
Meet hatchery production goals	Number of juvenile fish released - 250,000 yearlings	Future Brood Document (FBD) and hatchery records
Manage for adequate escapement where applicable	Hatchery return rates	Hatchery return records

<p>Minimize interactions with listed fish through proper broodstock management and mass marking. Maximize hatchery adult capture effectiveness. Use only hatchery fish</p>	<p>Number of broodstock collected - 174 adults for yearling program</p>	<p>Rack counts and CWT data Spawning guidelines</p>
	<p>Stray Rates</p>	<p>Hatchery records</p>
	<p>Sex ratios</p>	
	<p>Age structure</p>	<p>Spawning guidelines Hatchery records</p>
	<p>Timing of adult collection/spawning - August 1 thru September</p>	
	<p>Adherence to spawning guidelines - 1:1 with 5 fish pools</p>	
	<p>Total number of wild adults passed upstream - none (see section 2.2.3)</p>	
<p>Minimize interactions with listed fish through proper rearing and release strategies</p>	<p>Juveniles released as smolts</p>	<p>FBD and hatchery records FBD and historic natural outmigration times</p>
	<p>Out-migration timing of listed fish / hatchery fish April thru early June/ June</p>	<p>FBD and hatchery records</p>
	<p>Size and time of release 8 fpp/ June release</p>	<p>CWT data, mark/unmark ratios</p>
<p>Maintain stock integrity and genetic diversity</p>	<p>Effective population size</p>	<p>Spawning guidelines</p>
	<p>Hatchery-Origin Recruit spawners</p>	

<p>Maximize in-hatchery survival of broodstock and their progeny; and</p> <p>Limit the impact of pathogens associated with hatchery stocks, on listed fish</p>	<p>Fish pathologists will monitor the health of hatchery stocks on a monthly basis and recommend preventative actions / strategies to maintain fish health</p>	Co-Managers Disease Policy
	<p>Fish pathologists will diagnose fish health problems and minimize their impact</p>	Fish Health Monitoring Records
	<p>Vaccines will be administered when appropriate to protect fish health</p>	
	<p>A fish health database will be maintained to identify trends in fish health and disease and implement fish health management plans based on findings</p>	
	<p>Fish health staff will present workshops on fish health issues to provide continuing education to hatchery staff.</p>	
<p>Ensure hatchery operations comply with state and federal water quality standards through proper environmental monitoring</p>	NPDES compliance	Monthly NPDES reports

Benefits addressed:

- 1) Achieve broodstock collection/eggtake goals to provide fish for stable, predictable fisheries.
- 2) Communicate within WDFW and with the tribes, citizen groups, schools, private citizens and federal agencies regarding program goals and production objectives.
- 3) Meet Endangered Species Act recovery requirements and Wild Salmonid Policy

guidelines.

Risks addressed:

- 1) Reduce hatchery broodstock collection impacts on wild fish by initiating mass marking of hatchery chinook and returning wild fish entering the hatchery back to the river or stream.
- 2) Reduce interactions between hatchery and wild juvenile fish.
- 3) Maintain hatchery stock integrity and genetic diversity by:
 - a) continuing the policy of releasing no out-of-basin fall chinook from Hood Canal hatcheries or into Hood Canal streams
 - b) collecting sufficient broodstock to meet or exceed numbers of fish required to minimize effects of genetic drift
 - c) insuring that bias in taking broodstock is minimized, e.g., by taking fish throughout the run, by avoiding selection for size, incorporating some jacks into the broodstock.
- 4) Meet disease prevention and control standards in the Co-Manager's Salmonid Disease Control Policy.
- 5) Meet or exceed state and federal water-quality standards for hatchery discharge.

1.10.1) “Performance Indicators” addressing benefits.

- 1) Monitor the number of returning adults and eggtakes weekly to determine whether goals are being met.
- 2) Publish agreed-to production plans (Future Brood Document) with PNPTC tribes and other stakeholders.
- 3) Acquire needed permits (e.g. approved HGMP) to ensure that the Hood Canal yearling fall chinook program satisfies ESA recovery requirements for listed fish.

1.10.2) “Performance Indicators” addressing risks.

- 1) Report numbers and disposition of mass-marked hatchery-origin chinook and unmarked chinook returning to the facility.
- 2) Document freshwater spatial and temporal distribution of hatchery chinook in the river immediately after release. Adjust release strategies, if needed, to reduce interactions with wild fish.
- 3) Monitor run timing, size, sex ratio and other characters that might be subject to inadvertent directional selection during broodstock selection to ensure that the population

mean for these characters is not being altered.

4) Conduct genetic sampling once per generation to look for undesirable genetic effects (e.g. loss of alleles).

5) Conduct monthly visits by fish health specialists, more frequent checks if needed. Complete all required fish health reports documenting compliance with the Co-Manager's Salmonid Disease Control Policy.

6) Conduct water-quality testing and report results as required by the Washington Department of Ecology to document compliance with water-quality testing.

1.11) Expected size of program.

1.11.1) Proposed annual broodstock collection level (maximum number of adult fish).

To achieve the eggtake goal of 275,000 green eggs for the yearling program at Hoodspport Hatchery, a maximum of 174 fall chinook adults and 3 jacks will need to be collected. This assumes a 10 % pre-spawning mortality and a 91% egg-to smolt survival (Fuss and Ashbrook 1995), an average fecundity of 3,500 eggs per female, and a 1:1 sex ratio. Adults in excess of eggtake goals will be killed and sold.

1.11.2) Proposed annual fish release levels (maximum number) by life stage and location.

Life Stage	Release Location	Annual Release Level
Eyed Eggs		
Unfed Fry		
Fry		
Fingerling		
Yearling	Finch Creek (16.0222)	250,000

1.12) Current program performance, including estimated smolt-to-adult survival rates, adult production levels, and escapement levels. Indicate the source of these data.

Fishery and survival data from this program is limited at this time due to the newness of this program. The target fishery is the Puget Sound sport fishery. The 1994 broodyear (BY) released in 1996 survived at a rate of .12%. For the 95' BY the rate was 1.13%. The 96' BY is .1% (preliminary) at this time.

The escapement levels for the last 5 years to the Hood Canal have averaged 1,112 (includes Skokomish, Hamma Hamma, Dosewalips and the Duckabush rivers).

Broodstock levels back to the hatchery rack for brood years 1995 through 2001 were 3,190, 4,653, 8,342, 10,057, 10,976, 11,646 and 4,578, respectively.

1.13) Date program started (years in operation), or is expected to start.

The current production level of Hood Canal yearling fall chinook for on-site release at Hoodsport Hatchery began in 1995. There were intermittent releases from the hatchery since the 1986 brood but these have been primarily spring chinook. Sund Rocks Net Pens began releases with the 1989 brood chinook but was discontinued with the final plants made in 1999.

1.14) Expected duration of program.

Ongoing

1.15) Watersheds targeted by program.

Finch Creek (16.0222)

1.16) Indicate alternative actions considered for attaining program goals, and reasons why those actions are not being proposed.

None

SECTION 2. PROGRAM EFFECTS ON ESA-LISTED SALMONID POPULATIONS.

2.1) List all ESA permits or authorizations in hand for the hatchery program.

None

2.2) Provide descriptions, status, and projected take actions and levels for ESA-listed natural populations in the target area.

2.2.1) Description of ESA-listed salmonid population(s) affected by the program.

- Identify the ESA-listed population(s) that will be directly affected by the program.

None in Finch Creek.

- Identify the ESA-listed population(s) that may be incidentally affected by the program.

Puget Sound chinook, Hood Canal summer chum and Puget Sound bull trout.

We have no information on the adult age structure, sex ratio, size range or smolt distribution and emigration timing of wild chinook in Hood Canal streams. We do not know if Hood Canal hatchery-origin fingerling fall chinook interact with wild Hood Canal chinook. Hood Canal wild chinook are thought to emigrate mainly as sub-yearlings, probably from April through early June. The summer flows in the South Fork Skokomish River may be too low to support chinook through the summer, though some areas in the Lower North Fork do have sufficient water (C. Baranski, WDFW, personnel communication, March 2000). Hood Canal fall chinook spawn from mid-September through October with a peak in mid-October (WDFW and WWTIT 1994). Chinook spawning occurs in the mainstem Skokomish River, the lower South Fork Skokomish and tributaries such as Vance Creek, lower North Fork Skokomish and tributaries, and the lower reaches (below anadromous barriers) of Lilliwaup Creek, John Creek, the Duckabush, Dosewallips, Big and Little Quilcene Rivers, and the lower Union, Tahuya and Dewatto Rivers. Chinook spawning in many of these streams may be largely the result of hatchery releases.

Tissue samples of naturally-spawning fall chinook are being collected in Hood Canal streams for genetic analysis. Preliminary analysis of Skokomish basin adult spawners and juveniles suggests that the naturally-spawning chinook are largely, though perhaps not entirely, of George Adams/Hoodspout hatchery origin (memos from A. Marshall, WDFW, dated 4 May 1999 and 31 May, 2000).

Because there is no specific information on wild smolt temporal and spatial distribution in Hood Canal streams, the extent to which they might interact with hatchery chinook released locally is unknown.

Hood Canal Summer Chum:

Available data have been compiled in Tynan (1997) and the Summer Chum Salmon Conservation Initiative (WDFW and PNPTC, 2000).

Puget Sound Bull Trout (South Fork Skokomish stock (WDFW 1998)):

There is little or no information on adult age class structure, sex ratio, juvenile life history strategy or smolt emigration timing. Hood Canal Ranger District (Olympic National Forest) staff recently conducted a radio-tagging study of (presumed) bull trout in the South Fork Skokomish River (Ogg and Taiber 1999). The objectives of the study were to examine seasonal migration patterns and to identify spawning grounds and spawning times. In addition, Forest Service staff have been conducting trapping, snorkeling and electrofishing surveys for bull trout in the South Fork. They believe that fluvial and resident life history forms are present. There is no evidence from their work of an anadromous life history form, though anadromous fish may be present. Sexually mature fluvial fish range from 38 to 59 cm. During the course of the telemetry study, spawning migration activity in fluvial fish began in late October when the water temperature dropped below 7°C and river flow increased. Spawning time appears to be from late October through late November. Spawning grounds have tentatively been identified in

the mainstem South Fork from RM 18 through RM 23.5 and in Church, LeBar and Brown Creeks. Juvenile rearing areas include, but should not be considered restricted to, RM 19 through RM 23.5.

In general, chinook are not seen above the Gorge of the South Fork beginning at RM 7 (C. Baranski, WDFW, personnel communication, March, 2000) so interactions between hatchery chinook and bull trout are not expected unless fluvial or anadromous fish, if any, move downstream into the lower South Fork or the mainstem Skokomish River.

2.2.2) Status of ESA-listed salmonid population(s) affected by the program.

- Describe the status of the listed natural population(s) relative to “critical” and “viable” population thresholds

This has not been determined for the ESA listed population. WDFW SASSI document (1992) lists the following:

Summer/Fall chinook stock in Hood Canal is *healthy*.

Hood Canal summer chum stocks (WDFW and PNPTC, 2000):

1. Union River, *Healthy*
2. Lilliwaup and Jimmycomelately creeks, *critical*
3. Hamma Hamma, Duckabush, Dosewallips, Big/Little Quilcene, and Salmon/Snow Creek, *Depressed*

Puget Sound bull trout in Hood Canal are *viable*.

- Provide the most recent 12 year (e.g. 1988-present) progeny-to-parent ratios, survival data by life-stage, or other measures of productivity for the listed population. Indicate the source of these data.

No estimates of productivity are available for Puget Sound chinook or for Puget Sound bull trout in the Hood Canal region.

No good estimates of Hood Canal summer chum productivity are available because age data are not available. Recruit-per-spawner estimates done by WDFW, the NWIFC and PNPTC range from 1.5 to 1.8, but none of these are reliable at present (J. Ames, WDFW, personnel communication, February 2000).

- Provide the most recent 12 year (e.g. 1988-1999) annual spawning abundance estimates, or any other abundance information. Indicate the source of these data.

Table X. 1988-1998 spawner abundance data for Hood Canal fall chinook, Hood Canal summer chum and Lake Cushman bull trout/Dolly Varden. Chinook data are from the 1999 WDFW chinook run reconstruction. Summer chum data are from J. Ames

(WDFW, personnel communication). Bull trout data are from WDFW (1998) through 1996 and from D.Collins (WDFW, personnel communication) thereafter.

Table X

Year	Fall Chinook	Summer Chum	Bull Trout/Dolly Varden
1988	2,772	2,967	152
1989	1,425	598	174
1990	724	429	299
1991	1,858	746	299
1992	940	1,954	285
1993	1,172	712	412
1994	1,072	2,050	281
1995	1,999	8,971	250
1996	1,028	19,683	292
1997	492	8,420	No data collected
1998	1,803	3,407	119 ¹
1999	3,020 (prelim. est.)	3,884	90 ¹

- Provide the most recent 12 year (e.g. 1988-1999) estimates of annual proportions of direct hatchery-origin and listed natural-origin fish on natural spawning grounds, if known.

The proportions of direct Hoodspport Hatchery-origin yearling fall chinook and listed Puget Sound wild chinook on natural spawning grounds are unknown. Mass marking has not yet been initiated at Hoodspport and most Hoodspport fall chinook are not coded-wire tagged and adipose-fin clipped. Consequently, hatchery and wild fish are often indistinguishable on spawning grounds. However, in recent years hatchery-origin chinook, identified by adipose-fin clips and scale patterns, have been recovered from spawning grounds in the mainstem Skokomish River during sampling for genetic analysis. In 1998, 61 chinook spawners were sampled, ten of which were coded-wire tagged. They originated from George Adams hatchery (n=3), Hoodspport Hatchery (n=2), Long Live the Kings releases from Rick's Pond (n=4) and the now -defunct Sund Rock

¹ Counts were incomplete due to high water (D.Collins, personal communication, February, 2000)

net pens (n=1). Seven of these fish had been released as yearlings and three as fingerlings. Since George Adams releases only fingerlings, the yearlings would probably have come from the Long Live the Kings project, Hoodspout Hatchery or net pens in Hood Canal. Scale analysis of the untagged adults in the genetics sample showed that an additional 16 fish had hatchery yearling scale patterns. Thus hatchery-origin fish comprised at least 43% of the sample. More fish in the sample may have been of hatchery origin, but chinook released as fingerlings would have scale patterns indistinguishable from those of wild chinook which outmigrate mainly as fingerlings.

There is high potential for George Adams chinook released from Rick's Pond and from the now defunct net pen programs in lower Hood Canal to stray because they were released from sites to which they cannot return.

2.2.3) Describe hatchery activities, including associated monitoring and evaluation and research programs, that may lead to the take of listed fish in the target area, and provide estimated annual levels of take

- Describe hatchery activities that may lead to the take of listed salmonid populations in the target area, including how, where, and when the takes may occur, the risk potential for their occurrence, and the likely effects of the take.

Broodstock collection for the Hoodspout fall chinook program may result in take of listed Puget Sound fall chinook through capture at the trap at Finch Creek from August 1 through mid-September. Entry into the trap may result in injury to listed chinook. Listed wild chinook cannot be distinguished from unmarked hatchery fish, so they cannot be returned to Purdy Creek or the Skokomish River. The principal effect of this take is to remove listed chinook from the wild spawning population. The risk of this take is unknown because we do not know how many wild chinook are likely to enter Purdy Creek and reach the hatchery trap. Contact with chinook during spawner escapement surveys (August through October), carcass recovery programs (September and October), and other monitoring and evaluation programs has a potential to take listed chinook, but care is taken to not harm, harass, or otherwise disturb chinook spawners. The WDFW contact for Hood Canal-area surveys is Thom Johnson (johnsthi@dfw.wa.gov).

- Provide information regarding past takes associated with the hatchery program, (if known) including numbers taken, and observed injury or mortality levels for listed fish.

Because hatchery-origin and listed wild chinook cannot generally be distinguished in the trap or the adult holding pond, it is not possible to reasonably estimate the take of listed chinook (if any).

Provide projected annual take levels for listed fish by life stage (juvenile and adult) quantified (to the extent feasible) by the type of take resulting from the hatchery program (e.g. capture, handling, tagging, injury, or lethal take).

Annual take of listed wild Puget Sound chinook cannot be quantified since they cannot be distinguished from unmarked Hoodspout Hatchery chinook. If listed chinook are included in the hatchery broodstock, the likely sources of take resulting from Hoodspout Hatchery operations are broodstock collection, injury or mortality during spawning of adults, sampling of carcasses for scales, genetic stock identification, and routine monitoring and evaluation activities, incubation and rearing, injury or mortality during egg or fry transport to school or other co-operative programs, injury or mortality during rearing in co-operative programs, injury or mortality during on-station or off-station release.

- Indicate contingency plans for addressing situations where take levels within a given year have exceeded, or are projected to exceed, take levels described in this plan for the program.

Because take levels cannot be quantified, contingency plans to limit take to pre-determined numbers have not been developed at Hoodspout Hatcheries.

SECTION 3. RELATIONSHIP OF PROGRAM TO OTHER MANAGEMENT OBJECTIVES

3.1) Describe alignment of the hatchery program with any ESU-wide hatchery plan (e.g. Hood Canal Summer Chum Conservation Initiative) or other regionally accepted policies (e.g. the NPPC Annual Production Review Report and Recommendations - NPPC document 99-15). Explain any proposed deviations from the plan or policies.

The Hoodspout on-station fall chinook programs are conducted in a manner consistent with risk aversion measures in the Summer Chum Salmon Conservation Initiative (SCSCI) (WDFW and PNPTC 2000). Specifically, chinook are not released until after April 1 in order to reduce potential interactions with listed Hood Canal summer chum. Summer chum juveniles would be expected to migrate to salt water in February and March and then to swim seaward quickly (Tynan 1992); thus, clearing the area well before release of Hoodspout yearling chinook in May. The SCSCI considers that both juveniles and returning adults from the on-station program pose low risk for competition or predation to summer chum.

3.2) List all existing cooperative agreements, memoranda of understanding, memoranda of agreement, or other management plans or court orders under which program operates.

This HGMP is consistent with relevant standing orders and agreements. The Puget Sound Salmon Management Plan (PSSMP) and the Hood Canal Salmon Management Plan (HCSMP) are federal court orders that currently control both the harvest management rules and production schedules for salmon in Hood Canal under the *U.S. v. Washington* management framework. The parties to the SCSCI recognize that it may be necessary to modify these plans in order to implement the recommendations that will result from the SCSCI. However, the provisions of the PSSMP and HCSMP will remain

in effect until modified through court order by mutual agreement

3.3) Relationship to harvest objectives.

Tribal and non-Indian commercial and recreational fisheries directed at fall chinook and other species produced through WDFW hatchery releases will be managed to minimize incidental effects to listed chinook salmon and summer chum salmon. Time and area, gear-type restrictions, and chinook and summer chum release requirements will be applied to reduce takes of listed salmon in the Hood Canal mainstem, extreme terminal marine area, and river areas where these fisheries directed at other hatchery species occur. Compliance with the fisheries management strategy defined in the SCSCI will lead to fisheries on WDFW hatchery-origin stocks that are not likely to adversely affect listed chinook or listed summer chum.

Each year, state, federal and tribal fishery managers plan the Northwest's recreational and commercial salmon fisheries. This pre-season planning process is generally known as the North of Falcon process, which involves a series of public meetings between federal, state, tribal and industry representatives and other concerned citizens. The North of Falcon planning process coincides with meetings of the Pacific Fishery Management Council, which sets the ocean salmon seasons at these meetings.

For example, during 2000 as an outcome of the North of Falcon process, the state/tribal Puget Sound Chinook Harvest Management Plan (enclosed in letter from Billy Frank, Jr., NWIFC and Jeff Koenings, WDFW to Will Stelle, NMFS, dated February 15, 2000) contained proposals for the 2000/2001 fishing season.

For the 2001/2002 season, the co-manager's have prepared a Harvest Management Plan for Puget Sound Chinook Salmon. The Plan states specific objectives for harvest of the 15 Puget Sound management units, the technical bases for these objectives, and procedures for their implementation. The Plan assures that the survival and recovery of the Puget Sound ESU will not be impeded by fisheries-related mortality. The Plan is being submitted with the expectation that NMFS will reach a finding, based on the conditions stated in the 4(d) rule, that fisheries-related take in Washington waters is exempt from prohibition under Section 9 of the ESA. NMFS is/has reviewing/ed the Plan.

3.3.1) Describe fisheries benefitting from the program, and indicate harvest levels and rates for program-origin fish for the last twelve years (1988-99), if available.

Fishery data from this program is limited at this time due to the newness of this program. The target fishery is the Puget Sound sport fishery.

The 1994 brood year released in 1996 survived at a rate of .12%

The fishery distribution was: Columbia River Net: 1.6%
Puget Sound Sport: 27.4%
Hatchery: 71.0%

The state/tribal Puget Sound Chinook Harvest Management Plan (enclosed in letter from Billy Frank, Jr., NWIFC and Jeff Koenings, WDFW to Will Stelle, NMFS, dated February 15, 2000) contained proposals for the 2000/2001 fishing season. The proposed fisheries are designed to target George Adams and Hoodport Hatchery chinook while minimizing catch of wild chinook. The state/tribal FRAM for 2000/2001 fisheries projects a southern U.S. exploitation rate of <15% on mid-Hood Canal (Hamma Hamma, Duckabush and Dosewallips) wild chinook and <15% southern U.S. preterminal exploitation rate on Skokomish wild chinook. Final estimated southern U.S. exploitation rate on mid-Hood Canal wild chinook was 12.4% in FRAM run # 0700 dated 4-6-2000 (T Johnson, WDFW, personal communication).

3.4) Relationship to habitat protection and recovery strategies.

Hood Canal chinook: Limiting factors analyses have not been completed for Hood Canal natural chinook stocks and factors for decline and recovery are not available. However, since listed chinook and listed summer chum utilize similar habitats, habitat protection and recovery strategies designed to recover summer chum (see below) will also aid in the recovery of listed Hood Canal chinook.

Summer chum : Summer chum supplementation, habitat restoration and management measures are integrated as presented in the Summer Chum Salmon Conservation Initiative (WDFW and PNPTC 2000). The SCSCI provides a standardized approach to determine freshwater and estuarine limiting factors in each summer chum watershed. Habitat factors for decline and recovery for each watershed are described. In addition, at the summer chum ESU scale, protection and restoration strategies for each limiting factor for decline are provided. The goal of the habitat protections and restoration strategy is to maintain and recover the full array of watershed and estuarine-nearshore processes critical to the survival of summer chum across all life stages.

Bull Trout: Bull trout in the Hood Canal region are found in the South Fork Skokomish, Lake Cushman and the upper North Fork Skokomish above Staircase Falls. The condition of the South Fork is poor, as mentioned above. Lake Cushman is now a reservoir, and the water level in the one-half mile of the North Fork Skokomish just above the reservoir fluctuates too much to provide stable spawning habitat. Further, the upper and lower Cushman dams have eliminated the anadromous life history form from the North Fork. However, most of the North Fork above Lake Cushman is in the Olympic National Park and the habitat is essentially pristine.

Other Habitat Protection Efforts and Probable Benefits:

Habitat protection efforts include the Northwest Forest Plan, adopted by the Forest Service and the Bureau of Land Management in the Northwest in 1994. The plan requires increased stream buffers to protect stream habitat for salmonids and limits road construction and some forms of logging on steep/unstable slopes. Most of the Olympic National Forest is in Late Successional Reserves which limits logging to thinning in stands under 80 years old and severely limits or prohibits logging in older stands. The

Forest Service is updating road inventories and embarking on a long-term program to improve or close some of the roads which pose the greatest threats to slope stability and streams. Within Washington State, the Forests and Fish Report, prepared by the USFWS, NFMS, EPA, Office of the Governor of the State of Washington, WA DNR, WDFW, WA DOE, the Colville Tribes, Washington counties, and timber industry groups, was accepted by Washington Legislature in 1999. The emergency forest practices rules which were developed from the Report will result in some improvements in state and private forest land management including increased stream buffers and some reduction in logging in riparian areas and unstable upslope areas. Both the federal and state and private forest plans will result in habitat improvements, but are far from ideal for fish. The resulting improvements in fish habitat, such as increased large woody debris in streams, may not be realized for decades given the very poor current conditions of many fish-bearing streams and their riparian areas.

3.5) Ecological interactions.

Summer Chum: The SCSCI provides an assessment of risks to summer chum juveniles and adults posed by the production of Hoodspout fall chinook and summer chum, risk averse measures to implement, and monitoring and evaluation measures to be applied to minimize any risks.

Fall Chinook: Risks and benefits posed by hatchery-origin juvenile and adult chinook to wild juvenile and adult chinook will depend on the number, size, release time and stream residence time of the hatchery fish. Hoodspout Hatchery releases approximately 3.0 million fingerling smolts and 250,000 yearling smolts annually and production will be managed to minimize potential adverse effects to listed fall chinook.

Competition and Predation: Hoodspout yearling chinook are released directly into seawater and the marine water interaction with wild chinook is not well understood. These smolts are released at a size of about 188 mm (8 ffp) when wild Skokomish smolts are expected to be about 60 to 80 mm (108 to 255 ffp) long (D. Seiler, WDFW, personal communications, February, 2000). The USFWS (1994) has suggested that juvenile salmonids can consume fish which are one-third or less their own body length. Given this rule of thumb and approximate sizes of hatchery and wild fish at the time Hoodspout Hatchery chinook are released, predation by hatchery smolts is not expected to be a significant problem.

The numbers of wild chinook smolts have been estimated for the Skokomish basin and all of Hood Canal and are compared with numbers of hatchery chinook released in the table below.

Table 22. Comparison of wild and hatchery chinook smolts in the Skokomish River and in all of Hood Canal. Hatchery chinook include those released from George Adams, Hoodspout, Long Live the Kings, and the U of W at Big Beef Creek.

Area	Wild Smolts ¹	Hatchery Smolts	Hatchery Yearlings
Skokomish River	104,400	3,830,000	120,000
Hood Canal Streams	132,000	3,310,000 ²	250,000

¹Wild smolt numbers were estimated by averaging the 1995-1998 wild escapements in Hood Canal, halving that number to estimate the number of female spawners, applying a fecundity of 4,000 eggs per female (Bill Tweit, WDFW, personal communication) to estimate the total number of eggs produced, then applying a freshwater survival rate of 5% (Bill Tweit, WDFW, personal communication) to the egg estimate to estimate the number of surviving smolts.

²Includes 200,000 chinook released into Big Beef Creek by the University of Washington, 110,000 chinook released into the Hamma Hamma and 3,000,000 fingerlings released into Finch Creek by WDF&W.

The Species Interaction Working Group (SIWG) (1984) categorized various risks to wild salmon species and steelhead from hatchery-origin salmon species and steelhead. Their assessment of risks to wild chinook from hatchery chinook are summarized below.

Table. Risks posed by hatchery-origin chinook to wild chinook. Data from SIWG (1984).

Type of Risk	Level of Risk
Freshwater predation	Unknown_ *
Freshwater competition	High *
Early marine predation	Unknown
Early marine competition	High

* Note: There is no freshwater estuary on Finch Creek. The hatchery outfall is directly on Hood Canal so there is no freshwater residency for Hoodsport chinook.

The high risk of competition assumes significant temporal and spatial overlap between hatchery and wild juvenile chinook and increases when numbers of hatchery fish released are far larger than numbers of wild fish (SIWG 1984). We have no information on hatchery-wild overlaps in the Skokomish basin or in the waters of Hood Canal. Clearly the number of juvenile hatchery chinook greatly exceeds the estimated number of wild juveniles in the Skokomish basin and throughout Hood Canal which may increase the risk of competition or attraction of fish and avian predators.

Behavior modification: If large numbers of hatchery chinook are released into watersheds containing younger and/or smaller wild juveniles, they can stimulate

premature outmigration in wild fish via a Pied Piper effect (Hillman and Mullan 1989). Premature outmigration can reduce survival of wild fish because they would be smaller than normal size, making them more vulnerable to predation, and they may not have completed the physiological changes required to adapt to life in salt water. We do not know if this is a concern in the Skokomish basin.

Disease Transmission: The Hoodsport Hatchery operates under a standing NPDES permit that limits discharge effects on the environment and requires monitoring of effluent for settle-able and suspended solids. Adherence with the NPDES permit will likely lead to no adverse effects on water quality from the program on listed fish. It is possible that hatchery fish which have been infected by transmissible pathogens or effluent from hatcheries with sick fish could infect wild fish. Hatchery effluent is not tested for pathogens, so we do not know if Hoodsport is releasing pathogens into the environment. However, disease transmission from hatchery to wild fish does not appear to occur routinely, possibly because pathogen spread does not occur as readily in less crowded wild fish as in hatchery fish (Tynan 1999).

Adult Interactions: The ecological interactions between wild and hatchery adult chinook which are of special concern are competition for spawning areas and competition for mates. We have no specific information on possible competition. We know (see Section 2.2.2 above) that Hoodsport chinook do stray onto wild spawning grounds in the Skokomish basin, however, we do not know to what extent they compete with wild chinook.

Bull Trout: We have no information on interactions between Hoodsport chinook and wild bull trout in the Skokomish (the only watershed in the Hood Canal currently known to have native char). The risk of competition between hatchery chinook juveniles and bull trout is unknown. Presumably competition can occur where wild and hatchery fish overlap, and space or food are limiting, but juvenile distribution of bull trout in the South Fork Skokomish is not known in detail. South Fork Skokomish bull trout are found overwintering as far down as the confluence with the North Fork (L. Ogg, USFWS, Hood Canal Ranger District, personal communication, February, 2000) but whether they overlap with Hoodsport chinook when these fish are released in May is unknown. Predation risks to bull trout from hatchery chinook are likely to be low, since the smallest native char juveniles are likely to be found in the uppermost portions of the Skokomish watershed. By the time South Fork fluvial or possibly anadromous char reach lower river reaches where they are more likely to overlap with hatchery juveniles, they may be too large to be preyed upon. Spawning grounds of South Fork bull trout have not been identified in detail, but are unlikely to overlap with those of fall chinook, so competitive interactions on spawning grounds are unlikely to occur.

Bull trout from the North Fork Skokomish (Lake Cushman and Upper North Fork stocks) are unlikely to pass through the hydropower projects to interact with Hoodsport chinook.

SECTION 4. WATER SOURCE

4.1) Provide a quantitative and narrative description of the water source (spring, well, surface), water quality profile, and natural limitations to production attributable to the water source.

Hoodsport Hatchery: Water for rearing fall chinook yearlings at Hoodsport Hatchery comes from Finch Creek. The water right for Finch Creek is 17.4 cubic feet per second (cfs). Finch Creek is mostly spring-fed with additional run-off during rainy periods. Flows vary from 15 to 30 cfs with water temperatures ranging from 41 to 51 degrees Fahrenheit. Water quality in Finch Creek has deteriorated because of failing septic systems along Finch Creek. This has resulted in a beach closure to shellfish harvest at the mouth of Finch Creek due to pollution. Saltwater is supplied to Hoodsport Hatchery via two 20 HP vertical turbine pumps capable of pumping 2000 gallons per minute (gpm). Seawater is drawn through a pipeline connected to an intake located 80 feet deep in Hood Canal. Water right for the seawater is 8.8 cfs.

The yearling Hood Canal fall chinook at Hoodsport Hatchery are reared in Finch Creek water from egg to release. Because of the close proximity of Hoodsport Hatchery to Hood Canal, seawater from Hood Canal is added to the release ponds approximately 3 days prior to release. This is done in order help acclimate the yearlings to Hood Canal salinity, thus improving survival.

Hoodsport Hatchery operates under NPDES permit WAG-1011. There is no pollution abatement pond. Vacuumed pond wastes are applied to the property next to the hatchery. Hatchery effluent has not violated conditions of the permit. All intake screens meet NMFS and WDFW screening criteria.

4.2) Indicate risk aversion measures that will be applied to minimize the likelihood for the take of listed natural fish as a result of hatchery water withdrawal, screening, or effluent discharge.

Intake screens meet both NMFS and WDFW screening guidelines at Hoodsport Hatchery. This should minimize the risk that wild juvenile chinook might enter the freshwater intakes. Hoodsport Hatchery pond cleaning effluent is pumped onto a private upland disposal site and does not re-enter state waters. Hoodsport operates in compliance with NPDES discharge permit guidelines.

SECTION 5. FACILITIES

5.1) Broodstock collection facilities (or methods).

Hoodsport Hatchery: Broodstock are collected by installation of removable racks installed in a permanent weir in Finch Creek. Fish enter an adjacent fish ladder that leads them to three adult holding raceways with dimensions of 13' x 205' X 5'. The racks are installed on August 1 and removed in early December at the conclusion of the chum run.

5.2) Fish transportation equipment (description of pen, tank truck, or container used).

NA

5.3) Broodstock holding and spawning facilities.

Hoodsport Hatchery: Broodstock are held in the holding raceways until they are spawned. Spawning facilities are located at the head end of the raceways.

5.4) Incubation facilities.

Hoodsport Hatchery: Hood Canal fall chinook eggs are incubated to the eyed stage in vertical stack incubators at 5 pounds (lbs)/tray. Then they are shocked, picked and enumerated back into the vertical incubators at 5 lbs. per tray (approximately 9,000 chinook eggs per tray) and artificial substrate is added to the trays for hatching.

5.5) Rearing facilities.

Hoodsport Hatchery: The yearling portion of the Hood Canal fall chinook yearling program is reared in the standard raceways. They are split into the release ponds as they come available.

5.6) Acclimation/release facilities.

Hoodsport Hatchery: This group is reared in both standard raceways and the release ponds. Saltwater from Hood Canal can be pumped into either one for acclimation to seawater prior to release.

5.7) Describe operational difficulties or disasters that led to significant fish mortality.

None.

5.8) Indicate available back-up systems, and risk aversion measures that will be applied, that minimize the likelihood for the take of listed natural fish that may result from equipment failure, water loss, flooding, disease transmission, or other events that could lead to injury or mortality.

Hoodsport Hatchery is staffed full time with resident professional staff. The hatcheries are equipped with alarm systems and backup generator sets for providing auxiliary power in the event of a power failure.

SECTION 6. BROODSTOCK ORIGIN AND IDENTITY

Describe the origin and identity of broodstock used in the program, its ESA-listing status, annual collection goals, and relationship to wild fish of the same species/population.

6.1) Source.

The Hoodspport stock was started in 1952 with a release of Dungeness spring/summer chinook. This was followed by several years of Green River stock (Green River) releases until the stock became self sustaining. Additional inputs include chinook from Tumwater Falls (largely derived from Green River stock), Voights Creek (Puyallup basin), Big Beef Creek, Minter Creek and Trask River (Oregon) hatchery populations. The actual contribution of these hatcheries stocks to the Hoodspport stocks is unclear. Genetic analysis of the Hoodspport population showed similarities to the Marblemount (Skagit) Hatchery fall chinook population, which may reflect the mixed origin of both populations and the high reliance upon Green River origin broodstock..

Hoodspport stock shall be used to meet the program needs for the Hoodspport yearling program.

6.2) Supporting information.

6.2.1) History.

The Green River fall chinook stock originated from adults collected in the Green River. The stock was propagated at the Soos Creek Hatchery and disseminated widely throughout Puget Sound hatcheries. The hatchery began operation in 1901 and we assume that fall chinook broodstock collection began at that time.

Dungeness Chinook are a spring/summer stock native to the Dungeness. They were not successfully introduced at Hoodspport and may not have contributed significantly to the George Adams/Hoodspport stock.

The Voights Creek stock originated from Voights Creek chinook, but had significant infusions of Green River stock. The Minter Creek fall chinook stock is a Green River derivative. We do not know the origins of the Trask River chinook stock. These fish were incorporated into the Hoodspport stock because they tend to be large.

Hoodspport Hatchery has been self sufficient for 11 of the past 13 years (1988 to 2000). No intentional selection for any characters such as size or run timing has been conducted.

6.2.2) Annual size.

Wild chinook are not intentionally collected for broodstock. As mentioned earlier, it is not possible to distinguish wild chinook from unmarked hatchery fish, so if wild chinook enter the trap and adult holding pond, they will likely be spawned. The number of wild fish spawned, if any, is not known.

6.2.3) Past and proposed level of natural fish in broodstock.

Unknown.

6.2.4) Genetic or ecological differences.

Unknown

6.2.5) Reasons for choosing.

The Hoodspport Hatchery broodstock was the closest, locally adapted, stock and was selected for that reason.

6.3) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse genetic or ecological effects to listed natural fish that may occur as a result of broodstock selection practices.

Not applicable.

SECTION 7. BROODSTOCK COLLECTION

7.1) Life-history stage to be collected (adults, eggs, or juveniles).

Adults.

7.2) Collection or sampling design.

WDFW shall continue to use gametes procured from fall chinook salmon adults volunteering to the Hoodspport Hatchery to effect this program. The intent is to collect localized hatchery-origin broodstock at this location.

At Hoodspport Hatchery adult broodstock are collected at tidewater by installation of racks in Finch Creek, thus blocking upstream passage of adults. This forces adult broodstock to enter the fish ladder where they are trapped, sorted and held in three concrete raceways. The trap at Hoodspport Hatchery is operated from August 1 through the first week of December. The fall chinook are trapped between August 1 and mid-September. The trap consists of an instream weir with a removable rack to allow upstream passage between the 2nd week of December and July 31st. On "odd numbered" years, when pink salmon are returning, the barrier is installed the end of June. When the racks are installed fish are diverted to the adjacent fish ladder which leads them into the adult holding raceways. Fish can be diverted into any of 3 raceways and kept separate based on run timing, species, etc. There are no known features of this trap which would lead to the collection of a non-representative sample of broodstock. The trap is only closed temporarily when the maximum carrying capacity is reached.

7.3) Identity.

Unmarked hatchery-origin chinook cannot presently be distinguished from wild fish.

7.4) Proposed number to be collected:

7.4.1) Program goal (assuming 1:1 sex ratio for adults):

To achieve the eggtake goal of 275,000 green eggs for the yearling program at Hoodsport Hatchery, a maximum of 174 fall chinook adults and 3 jacks will need to be collected. This assumes a 10 % pre-spawning mortality and a 91% egg-to smolt survival (Fuss and Ashbrook 1995), an average fecundity of 3,500 eggs per female, and a 1:1 sex ratio. Adults in excess of eggtake goals will be killed and sold

7.4.2) Broodstock collection levels for the last twelve years (e.g. 1988-99), or for most recent years available:

Hoodsport Hatchery:

Year	Adults			Eggs	Juveniles
	Males	Females	Jacks		
1988	3,200	2,059	35	8,932,000	
1989	1,598	1,904	20	8,404,000	
1990	777	434	10	1,875,000	
1991	1,449	1,118	15	5,249,000	
1992	564	367	7	1,608,500	
1993	1,226	779	15	3,468,000	
1994	980	886	12	3,780,000	
1995	702	864	18	3,888,000	
1996	1,346	1,271	15	5,426,600	
1997	2,080	1,994	9	8,293,800	
1998	1,631	1,595	8	6,661,400	
1999	804	860	10	3,322,000	
2000	993	861	16	3,990,000	
2001	508	511	20	2,303,150	

7.5) Disposition of hatchery-origin fish collected in surplus of broodstock needs.

All returning fall chinook are trapped at the Hoodsport Hatchery. There are no allowable upstream escapement levels at Hoodsport. Adult fall chinook males in excess of a 1:1 ratio with females are killed and sold to the contract vendor or donated for tribal ceremonial use, food banks, nutrient enhancement, etc. Females with green, bloody, or water-hardened eggs are culled out of the spawning population. Ripe females, in excess of program need, are sold or donated in the same manner as excess males.

7.6) Fish transportation and holding methods.

NA

7.7) Describe fish health maintenance and sanitation procedures applied.

Fish health and sanitation measures are consistent with the Co-Managers Salmonid Disease Control Policy (NWIFC and WDFW 1998). Broodstock females used for the yearling program at Hoodspport Hatchery are injected with liquid erythromycin for control of Bacterial Kidney Disease (BKD). They are also subjected to an Enzyme Linked Immunosorbant Assay (ELISA) screening for BKD. Only eggs from below-low titer females are used for the yearling production. A similar approach is being considered for the broodstock that make up the yearling program originating from George Adams Hatchery.

A representative sample of broodstock from Hoodspport Hatchery are routinely sampled for virus as required by this Co-Managers Salmonid Disease Control Policy.

7.8) Disposition of carcasses.

The disposition of chinook carcasses at Hoodspport Hatchery depends upon the condition of the carcasses and whether the fish have been injected with drugs. Drug-treated fish are buried on-station or in a local landfill. Carcasses of untreated fish, both spawned and unspawned, may be sold to a contracted buyer, donated for tribal ceremonial purposes, or donated to a local food bank.

7.9) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse genetic or ecological effects to listed natural fish resulting from the broodstock collection program.

No special risk aversion measures are in place to protect listed wild fish since unmarked hatchery and wild fish can not be distinguished at this time.

SECTION 8. MATING

Describe fish mating procedures that will be used, including those applied to meet performance indicators identified previously.

8.1) Selection method.

All ripe fish are selected randomly for spawning from available broodstock.

8.2) Males.

Males are selected randomly and mated in 5 X 5 pools with the females. Jacks are spawned at no more than 2 % of the total males as required by the WDFW Hatchery Spawning Guidelines (Seidel 1983).

8.3) Fertilization.

Eggs and milt are mixed in 5 X 5 pools, and allowed to sit for 10 minutes. Fertilized eggs are pooled and taken into the hatchery for distribution into the incubators. All eggs are disinfected with iodine at 100 ppm for 1 hour during water-hardening as required by the Co-Managers Salmonid Disease Control Policy (1998).

8.4) Cryopreserved gametes.

Not used.

8.5) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse genetic or ecological effects to listed natural fish resulting from the mating scheme.

No wild-origin adults will be knowingly spawned.

SECTION 9. INCUBATION AND REARING -

Specify any management *goals* (e.g. “egg to smolt survival”) that the hatchery is currently operating under for the hatchery stock in the appropriate sections below. Provide data on the success of meeting the desired hatchery goals.

9.1) Incubation:

9.1.1) Number of eggs taken and survival rates to eye-up and/or ponding.

From Hood Canal Operational Plan:

Green Egg to Fry Survival: Range of 92.0% to 96.2%

Fry to Fingerling Smolt Survival: Range of 86.8% to 98.8%

9.1.2) Cause for, and disposition of surplus egg takes.

Program intent is not to exceed eggtake goals established in the Future Brood Document. If survival is greater than anticipated, excess fry will be planted in landlocked lakes.

9.1.3) Loading densities applied during incubation.

Hoodsport Hatchery green eggs are eyed in vertical incubators at 5.5 lbs. per tray and hatched at 7,500 eggs per tray in artificial substrate with an inflow of 4 gpm. Average green egg size is 1,700 eggs per pound.

9.1.4) Incubation conditions.

At Hoodsport Hatchery eggs are incubated and hatched on surface water from Finch Creek. Incubator trays are "rodded" as needed during dirty water conditions. Temperatures during incubation vary from 41 to 45 degrees Fahrenheit. Water flows are visually checked daily.

9.1.5) Ponding.

Fry are forced ponded when yolk absorption is 95 %+ complete. At Hoodsport Hatchery ponding occurs between January 1 and the first week of February. Accumulated Temperature Units (TU's) at ponding are 1,680.

9.1.6) Fish health maintenance and monitoring.

Eggs at Hoodsport are treated with Paracide-F (Formalin) at a rate of 1: 600 for 15 minutes daily beginning 24 hours after spawning until 3 days prior to hatching. Fish health is monitored on a routine basis by the Area Fish Health Specialist. If needed, treatment plans are prescribed in accordance with the WDFW Fish Health Manual and Policies.

9.1.7) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse genetic and ecological effects to listed fish during incubation.

Not applicable.

9.2) Rearing:

9.2.1) Provide survival rate data (*average program performance*) by hatchery life stage (fry to fingerling; fingerling to smolt) for the most recent twelve years (1988-99), or for years dependable data are available..

From Hood Canal Operational Plan:

Fry to smolt survival 1984-88 averages 87.2%

9.2.2) Density and loading criteria (goals and actual levels).

In general, loading and density levels conform to standards set forth in Piper, et al., 1982.

9.2.3) Fish rearing conditions

Waste is vacuumed out of raceways weekly. Release ponds cannot be cleaned during rearing. Pond flows are measured weekly and feed levels adjusted accordingly. Mortality is removed daily and screens are cleaned daily. Maximum and minimum temperatures are also measured daily. Loadings are kept at or below standards set forth in Piper, et al., 1982.

9.2.4) Indicate biweekly or monthly fish growth information (*average program performance*), including length, weight, and condition factor data collected during rearing, if available.

Not available.

9.2.5) Indicate monthly fish growth rate and energy reserve data (*average program performance*), if available.

Not available.

9.2.6) Indicate food type used, daily application schedule, feeding rate range (e.g. % B.W./day and lbs/gpm inflow), and estimates of total food conversion efficiency during rearing (*average program performance*).

All fish in the Hood Canal fall chinook yearling program are started on BioDiet Starter and switched to BioDiet Grower. Manufacturer recommendations are followed regarding when to switch pellet sizes. Feed is fed by hand. Daily feeding frequency is gradually decreased from 5 times per day at ponding to 1 time per day/5 days per week at release.

9.2.7) Fish health monitoring, disease treatment, and sanitation procedures.

See 9.1.6

9.2.8) Smolt development indices (e.g. gill ATPase activity), if applicable.

Physical appearance and behavior are used to judge smolt development.

9.2.9) Indicate the use of "natural" rearing methods as applied in the program.

None used for yearling program.

9.2.10) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse genetic and ecological effects to listed fish under propagation.

NA

SECTION 10. RELEASE

Describe fish release levels, and release practices applied through the hatchery program.

10.1) Proposed fish release levels.

Age Class	Maximum Number	Size (fpp)	Release Date	Location
Eggs				
Unfed Fry				
Fry				
Fingerling				
Yearling	250,000	8 fpp	June 1	Finch Creek (16.0222)

10.2) Specific location(s) of proposed release(s).

Stream, river, or watercourse: Finch Creek (16.0222)
Release point: Finch Creek (mouth/confluence with Hood Canal)
Major watershed: Hood Canal
Basin or Region: Hood Canal (Puget Sound)

10.3) Actual numbers and sizes of fish released by age class through the program.

Release year	Eggs/ Unfed Fry	Avg size	Fry	Avg size	Fingerling	Avg size	Yearling	Avg size
1988								
1989							33,700	7 fpp
1990								
1991							186,700	5 fpp
1992								

Release year	Eggs/ Unfed Fry	Avg size	Fry	Avg size	Fingerling	Avg size	Yearling	Avg size
1993								
1994							28,800	8 fpp
1995							22,400	7 fpp
1996							53,500	5 fpp
1997							252,867	8 fpp
1998							257,799	6 fpp
1999							249,797	8 fpp
2000							253,611	7 fpp
2001							247,931	6 fpp
Average							158,711	7 fpp

10.4) Actual dates of release and description of release protocols.

At Hoodspport Hatchery the fall chinook yearlings are forced released at night on an incoming tide. Fish are released within date and size parameters, as outlined in the Future Brood Document and the SCSCI.

10.5) Fish transportation procedures, if applicable.

No fish are transported for off-station release.

10.6) Acclimation procedures

At Hoodspport Hatchery saltwater is pumped into the yearling release pond to gradually acclimate the fish to saltwater prior to release.

10.7) Marks applied, and proportions of the total hatchery population marked, to identify hatchery adults.

For Hoodspport Hatchery releases: 1995 brood = 38% Ad+CWT. '96 brood = 99% Ad+CWT. '97 brood = 99% Ad+CWT. '98 brood = none cwt'd

With co-manager agreement, WDF&W will apply an identifiable mark to 100% of the fall chinook production released through the Hoodspport Hatchery program each year to allow monitoring and evaluation of the hatchery program fish releases and adult returns. WDFW shall apply a coded-wire tags to a portion of the fall chinook production to allow

for the evaluation of fishery contribution, survival rates and stray levels to other Puget Sound watersheds.

10.8) Disposition plans for fish identified at the time of release as surplus to programmed or approved levels.

None anticipated as fish are inventoried several times during their hatchery life cycle.

10.9) Fish health certification procedures applied pre-release.

Representative fish are examined by a WDFW Fish Health Specialist prior to release or transfer, in accordance with the Co-Managers Salmonid Disease Control Policy.

10.10) Emergency release procedures in response to flooding or water system failure.

In the event of a water system failure, screens would be pulled to allow fish to exit the pond. In some cases they can be transferred into other rearing vessels to prevent an emergency release. WDFW also has emergency response procedures for providing back-up pumps, transport trucks, etc. in cases of emergency. In cases of severe flooding the screens are not pulled because flood waters rise to the point where they breach the ponds. Past experience has shown that the fish tend to lay on the bottom of the pond during flooding events and only those that are inadvertently swept out are able to leave.

10.11) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse genetic and ecological effects to listed fish resulting from fish releases.

The yearlings released from Hoodspout Hatchery are released directly into saltwater minimizing freshwater interaction with naturally-produced fall chinook.

SECTION 11. MONITORING AND EVALUATION OF PERFORMANCE INDICATORS

11.1) Monitoring and evaluation of “Performance Indicators” presented in Section 1.10.

Note: See section 1.10 for Monitoring and Evaluation. The purpose of a monitoring program is to identify and evaluate the benefits and risks which may derive from the hatchery program. The monitoring program is designed to answer questions of whether the hatchery is providing the benefits intended, while also minimizing or eliminating the risks inherent in the program. A key tool in any monitoring program is having a mechanism to identify each hatchery production group.

Each production group shall be identified with distinct otolith marks, adipose clips, coded wire tags, blank wire tags or other identification methods as they become available, to allow for evaluation of each particular rearing and/or release strategy. This will allow for selective harvest on hatchery stocks when appropriate, monitoring of interactions of hatchery and wild fish wherever they co-mingle in riverine, estuarine and marine habitats and assessment of the status of the target population. WDFW shall monitor the Chinook salmon escapement into the target and non-target Chinook populations to estimate the number of tagged, un-tagged and marked fish escaping into the river each year and the stray rates of hatchery Chinook into the rivers.

11.1.1) Describe plans and methods proposed to collect data necessary to respond to each “Performance Indicator” identified for the program.

Benefit Indicator 1: Achieve broodstock/eggtake goals to provide fish for stable, predictable fishery

The maximum number of spawners needed to meet the yearling program eggtake has been determined to be 174 fall chinook adults. Because fish are not sorted by sex at the time they enter the adult pond from the trap, more chinook will be collected to assure that the program needs are met. The number of spawning days is planned in advance, based on typical return timing. The number of males and females to be spawned on each day can be determined. The risk is that the number of females will fall short of the number needed, and eggtake will be less than required.

Egg takes are estimated at the time of spawning and refined after shocking and picking.

Benefit Indicator 2: Communicate within WDFW and with tribes, citizen groups, private citizens and federal agencies regarding program goals and production objectives. Meet ESA recovery requirements and Wild Salmonid Policy requirements.

There is no formal process for reviewing program goals and production objectives. Typically WDFW Region 6 staff and PNPTC/tribal staff communicate if production changes are proposed. Production changes involving the regional fish enhancement group or volunteer co-op groups are communicated through the WDFW Cooperative Extension, Outreach and Partnership Program. The changes in goals and production levels which result from these discussions are reflected in the Future Brood Document compiled by WDFW. Recently NMFS has also become involved in discussions of changes to production at Hoodsport hatchery affecting the region fish enhancement program.

WDFW and NMFS are engaged in discussions of hatchery chinook production and release in Hood Canal to ensure that agency hatchery programs are consistent with recovery requirements. Aspects of hatchery physical plant and operations which may

conflict with the Wild Salmonid Policy will be reviewed by WDFW staff assigned to implement the policy.

Risk Indicator 1: Reduce hatchery broodstock collection impacts on wild fish

In order to minimize collection of wild chinook for spawning, they must be separable from all hatchery chinook. This is currently not possible for two reasons. First, we cannot currently distinguish unmarked hatchery fish from wild fish. Second, we have no way to physically separate hatchery and wild fish entering the hatchery. There is no sorting capability either at the adult trap or in the adult holding pond.

The problem of distinguishing wild from hatchery fish could be addressed by marking all hatchery fish. The state and the PNPT tribes are discussing the need to mass mark chinook in Hood Canal. The problem of separating hatchery and wild fish once they can be identified could be solved if the adult pond could be divided and a sorter were installed at the trap or the entrance to the pond. Once wild fish can be sorted from hatchery fish, they can be returned to the Hood Canal for release. We must be aware, however, that even with mass marking, a small number of unmarked hatchery fish may return depending on the proportion of "bad clips or marks" at the time of marking.

Risk Indicator 2: Reduce interactions between hatchery and wild juvenile fish.

This would require monitoring of hatchery smolts following release from Finch Creek and determination of the temporal and spatial distribution of juvenile hatchery fingerlings and wild salmonids.

Risk Indicator 3: Maintain hatchery stock integrity and genetic diversity.

This requires that no chinook from outside the Hood Canal region be introduced into Hoodsport Hatchery. It also requires that the spawning population be sufficiently large to avoid significant effects of genetic drift and that spawners represent the entire run timing.

Risk Indicator 4: Meet disease prevention and control standards in co-managers Salmonid Disease Policy.

This requires that measures prescribed for examining fish to be transferred or released be followed, that routine health inspections be conducted and that disease outbreaks be contained quickly.

11.1.2) Indicate whether funding, staffing, and other support logistics are available or committed to allow implementation of the monitoring and evaluation program.

Funding and resources are currently committed to monitor and evaluate this program as detailed in the Resource Management Plan for Puget Sound Chinook Salmon Hatcheries (Washington Department of Fish and Wildlife and Puget Sound Treaty Tribes, August 23, 2002).

Benefit Indicator 1: Staff and funding to count hatchery adult returns and determine eggtake needs are available.

Benefit Indicator 2: Staff and funding are available to carry out discussions of production programs at Hoodspport and to make changes to the Future Brood Document to reflect those changes.

Risk Indicator 1: Funding is not currently available to construct a means of separating wild and hatchery fish at the hatchery.

Risk Indicator 2: The staff, funding and logistical support are not available to undertake monitoring of hatchery smolts, determination of the extent to which they overlap with wild fish and the effect of that overlap.

Risk Indicator 4: Disease prevention and control measures are monitored in the monthly fish health reports for Hoodspport Hatchery.

Risk Indicator 5: Water quality is monitored in the monthly Discharge Monitoring Report, part of the NPDES permit reporting requirements.

11.2) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse genetic and ecological effects to listed fish resulting from monitoring and evaluation activities.

It is anticipated that adherence to monitoring and evaluation protocols will not elevate risk to listed chinook salmon.

SECTION 12. RESEARCH

12.1) Objective or purpose.

None.

12.2) Cooperating and funding agencies.

12.3) Principle investigator or project supervisor and staff.

12.4) Status of stock, particularly the group affected by project, if different than the stock(s) described in Section 2.

12.5) Techniques: include capture methods, drugs, samples collected, tags applied.

12.6) Dates or time period in which research activity occurs.

12.7) Care and maintenance of live fish or eggs, holding duration, transport methods.

12.8) Expected type and effects of take and potential for injury or mortality.

12.9) Level of take of listed fish: number or range of fish handled, injured, or killed by sex, age, or size, if not already indicated in Section 2 and the attached “take table” (Table 1).

12.10) Alternative methods to achieve project objectives.

12.11) List species similar or related to the threatened species; provide number and causes of mortality related to this research project.

12.12) Indicate risk aversion measures that will be applied to minimize the likelihood for adverse ecological effects, injury, or mortality to listed fish as a result of the proposed research activities.

SECTION 14. CERTIFICATION LANGUAGE AND SIGNATURE OF RESPONSIBLE PARTY

“I hereby certify that the foregoing information is complete, true and correct to the best of my knowledge and belief. I understand that the information provided in this HGMP is submitted for the purpose of receiving limits from take prohibitions specified under the Endangered Species Act of 1973 (16 U.S.C.1531-1543) and regulations promulgated thereafter for the proposed hatchery program, and that any false statement may subject me to the criminal penalties of 18 U.S.C. 1001, or penalties provided under the Endangered Species Act of 1973.”

Name, Title, and Signature of Applicant:

Certified by _____ Date: _____

Table 1. Estimated listed salmonid take levels of by hatchery activity.

Listed species affected: Chinook ESU/Population: Puget Sound Activity: Yearling Chinook Program				
Location of hatchery activity: Hoodport Hatchery (Hood Canal) Dates of activity: Sept-August Hatchery program operator: WDFW				
Type of Take	Annual Take of Listed Fish By Life Stage (<i>Number of Fish</i>)			
	Egg/Fry	Juvenile/Smolt	Adult	Carcass
Observe or harass a)				
Collect for transport b)				
Capture, handle, and release c)				
Capture, handle, tag/mark/tissue sample, and release d)				
Removal (e.g. broodstock) e)			Unknown	
Intentional lethal take f)				
Unintentional lethal take g)	Unknown	Unknown	Unknown	
Other Take (specify) h)				

- a. Contact with listed fish through stream surveys, carcass and mark recovery projects, or migrational delay at weirs.
- b. Take associated with weir or trapping operations where listed fish are captured and transported for release.
- c. Take associated with weir or trapping operations where listed fish are captured, handled and released upstream or downstream.
- d. Take occurring due to tagging and/or bio-sampling of fish collected through trapping operations prior to upstream or downstream release, or through carcass recovery programs.
- e. Listed fish removed from the wild and collected for use as broodstock.
- f. Intentional mortality of listed fish, usually as a result of spawning as broodstock.
- g. Unintentional mortality of listed fish, including loss of fish during transport or holding prior to spawning or prior to release into the wild, or, for integrated programs, mortalities during incubation and rearing.
- h. Other takes not identified above as a category.
